Research has been done with pulsed-laser evaporated B, Be and Mg atoms and molecular hydrogen to explore the reactivities of these metals with H₂ and to investigate infrared spectra of the product molecules in solid argon. The major products in the B/H₂ system were BH, (H₂BH), Bh₃, (H₂) (BH₃) and B₂H₆. It is clear that molecular hydrogen is complexed to BH and BH₃ in these experiments. Pulsed laser ablated boron atoms have been reacted with NH₃, CH₃NH₂ and NO to form novel boron insertion products which have been trapped in solid argon for infrared spectroscopic study. This work makes two important contributions. First, laser ablated boron atoms are shown to be highly reactive. Second, the importance of isotopic substitution for matching experimental observed and theoretical calculated frequencies for new molecules is clearly demonstrated.

Boron Atom Matrix Chemistry

June 1, 1993 to October 31, 1996

ACCOMPLISHMENTS

Research has been done with pulsed-laser evaporated B, Be and Mg atoms and molecular hydrogen to explore the reactivities of these metals with H₂ and to investigate infrared spectra of the product molecules in solid argon. The major products in the B/H₂ system were BH, (H₂)(BH), BH₃, (H₂)(BH₃) and B₂H₆. It is clear that molecular hydrogen is complexed to BH and BH₃ in these experiments.

In the case of Be and Mg, the major products were the linear dihydride H-M-H and the monohydride M-H molecules. This work obtained the first experimental evidence for H-Be-H, which is the textbook example of sp hybridized bonding.

Pulsed laser ablated boron atoms have been reacted with NH₃, CH₃NH₂ and NO to form novel boron insertion products which have been trapped in solid argon for infrared spectroscopic study.

The major reaction products of laser-ablated B atoms with NH₃ are iminoborane, H-B≡N-H, formed by B insertion and H elimination, and BNBH, formed by a second B insertion and H elimination. These novel molecules were identified by isotopic substitution and comparison to *ab initio* calculated frequencies.

Reactions of B with CH₃NH₂ give the same HB≡NH and BNBH products and both methyliminoborane isomers CH₃B≡NH and HB≡NCH₃. The methyliminoborane molecules are isoelectronic with methylacetylene. It appears that B inserts into the C-N and N-H bonds with comparable facility, but there is little evidence for insertion into C-H bonds in these experiments.

The major B atom reaction with NO is insertion to form triplet NBO which is identified from B-O stretching and NBO bending modes at 1996.8 and 493.5 cm⁻¹, respectively, through isotopic substitution and MP2 frequency calculations. Triplet NBO is a high energy density matter candidate. A second B atom adds to give BNBO also identified by 2068.2 and 500.9 cm⁻¹ absorptions in the same regions.

Several of these products are highly reactive molecular species that might have possible applications as high energy density materials, in particular, iminoborane, the methyliminoboranes and NBO.

This work makes two important contributions. First, laser ablated boron atoms are shown to be highly reactive. Second, the importance of isotopic substitution for matching experimental observed and theoretical calculated frequencies for new molecules is clearly demonstrated.
